# 1 Operations Research

**Ex. 1** — **coses**Consider a manufacturing company that produces two products,  $P_1$  and  $P_2$ . The company aims to maximize its profit. The profit from each product is given as follows:

-  $P_1$ : \$40 per unit -  $P_2$ : \$30 per unit

The company has the following constraints based on its resources:

1. The availability of raw material limits production to a maximum of 100 units of  $P_1$  and 80 units of  $P_2$ . 2. The total production time available is 160 hours, where producing one unit of  $P_1$  takes 2 hours and one unit of  $P_2$  takes 1 hour.

Can you formulate the operations research problem?

**Answer (Ex. 1)** — The problem can be stated as:

Objective Function: Maximize  $Z = 40x_1 + 30x_2$ Subject to:

> $2x_1 + x_2 \le 160$  (Total production time constraint)  $x_1 \le 100$  (Raw material constraint for  $P_1$ )  $x_2 \le 80$  (Raw material constraint for  $P_2$ )  $x_1, x_2 \ge 0$  (Non-negativity constraints)

## 1.1 Non-linear optimization

**Ex. 2** — **coses**A company wants to maximize its profit function given by:

$$f(x,y) = -x^2 + 4xy - 2y^2$$

where x and y represent the amount of resources allocated to two different projects.

The problem is subject to the following constraints:

1. The total resources used must not exceed 30 units:

$$x + 2y \le 30$$

2. The product of the resources allocated must be at least 50 units:

$$xy \ge 50$$

3. The relationship between the resource allocations must satisfy the following nonlinear constraint:

$$y \le \frac{3x^2}{100} + 5$$

The company wants to find the values of x and y that maximize the profit f(x,y) under these constraints.

Can you help the company drawing the problem in a graph? Can you identify the feasible region? Is the region convex?

Answer (Ex. 2) — This is 2.

A company wants to maximize its profit function given by:

$$f(x,y) = -x^2 + 4xy - 2y^2$$

where x and y represent the amount of resources allocated to two different projects.

The problem is subject to the following constraints:

1. The total resources used must not exceed 30 units:

$$x + 2y \le 30$$

2. The product of the resources allocated must be at least 50 units:

$$xy \ge 50$$

3. The relationship between the resource allocations must satisfy the following nonlinear constraint:

$$y \le \frac{3x^2}{100} + 5$$

Find the values of x and y that maximize the profit f(x,y) under these constraints.

The problem is shown in Figure 1.

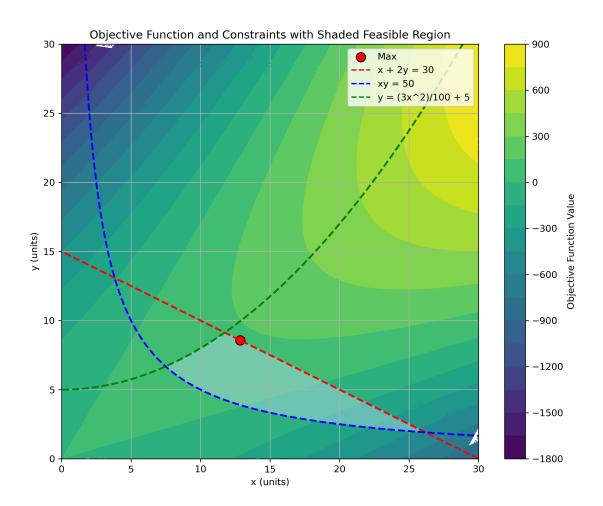

Figure 1: Contour plot of the objective function  $f(x,y)=-x^2+4xy-2y^2$  with constraints  $x+2y\leq 30$  (red dashed),  $xy\geq 50$  (blue dashed), and  $y\leq \frac{3x^2}{100}+5$  (green dashed). The light blue region represents the feasible area where all constraints are satisfied. The solution obtained with Code 1

## 1.1.1 Lagrange Multipliers

**Ex. 3** — Optimization of  $f(x,y) = x^2 - y$  subject to  $x^2 + y^2 = 4$ 

5

Answer (Ex. 3) — We will use the method of Lagrange multipliers. Step 1: Define the Lagrange Function Define the constraint as  $g(x,y) = x^2 + y^2 - 4 = 0$ . The Lagrange function is then:

$$\mathcal{L}(x, y, \lambda) = f(x, y) + \lambda \cdot g(x, y) = x^2 - y + \lambda(x^2 + y^2 - 4).$$

Step 2: Compute the Partial Derivatives We now compute the partial derivatives of  $\mathcal{L}(x, y, \lambda)$  with respect to x, y, and  $\lambda$ :

$$\frac{\partial \mathcal{L}}{\partial x} = 2x + \lambda \cdot 2x = 2x(1+\lambda) = 0,$$

$$\frac{\partial \mathcal{L}}{\partial y} = -1 + \lambda \cdot 2y = 0 \quad \Rightarrow \quad \lambda = \frac{1}{2y},$$

$$\frac{\partial \mathcal{L}}{\partial \lambda} = x^2 + y^2 - 4 = 0.$$

#### Step 3: Solve the Equations

From  $\frac{\partial \mathcal{L}}{\partial x} = 0$ :

$$2x(1+\lambda) = 0.$$

This gives two possibilities:

- x=0, or
- $1 + \lambda = 0 \implies \lambda = -1$ .

Case 1: x = 0 Substitute x = 0 into the constraint equation  $x^2 + y^2 = 4$ :

$$0^2 + y^2 = 4$$
  $\Rightarrow$   $y^2 = 4$   $\Rightarrow$   $y = \pm 2$ .

For y = 2, substitute into  $f(x, y) = x^2 - y$ :

$$f(0,2) = 0^2 - 2 = -2.$$

For y = -2, substitute into f(x, y):

$$f(0,-2) = 0^2 - (-2) = 2.$$

Case 2:  $\lambda = -1$  Substitute  $\lambda = -1$  into  $\lambda = \frac{1}{2y}$ :

$$-1 = \frac{1}{2y} \quad \Rightarrow \quad y = -\frac{1}{2}.$$

Now, substitute  $y = -\frac{1}{2}$  into the constraint equation  $x^2 + y^2 = 4$ :

$$x^{2} + \left(-\frac{1}{2}\right)^{2} = 4 \quad \Rightarrow \quad x^{2} + \frac{1}{4} = 4 \quad \Rightarrow \quad x^{2} = \frac{15}{4} \quad \Rightarrow \quad x = \pm \frac{\sqrt{15}}{2}.$$

Now, calculate  $f(x,y)=x^2-y$  for  $y=-\frac{1}{2}$  and  $x=\pm\frac{\sqrt{15}}{2}$ : For  $x=\frac{\sqrt{15}}{2}$ :

$$f\left(\frac{\sqrt{15}}{2}, -\frac{1}{2}\right) = \left(\frac{\sqrt{15}}{2}\right)^2 - \left(-\frac{1}{2}\right) = \frac{15}{4} + \frac{1}{2} = \frac{17}{4}.$$

For  $x = -\frac{\sqrt{15}}{2}$ :

$$f\left(-\frac{\sqrt{15}}{2}, -\frac{1}{2}\right) = \left(-\frac{\sqrt{15}}{2}\right)^2 - \left(-\frac{1}{2}\right) = \frac{15}{4} + \frac{1}{2} = \frac{17}{4}.$$

Step 4: Compare the Results We now compare the function values:

- For (0,2): f(0,2) = -2.
- For (0,-2): f(0,-2) = 2.
- For  $\left(\frac{\sqrt{15}}{2}, -\frac{1}{2}\right)$  and  $\left(-\frac{\sqrt{15}}{2}, -\frac{1}{2}\right)$ :  $f = \frac{17}{4} \approx 4.25$ .

Conclusion

- The maximum value is  $f = \frac{17}{4} \approx 4.25$  at  $\left(\frac{\sqrt{15}}{2}, -\frac{1}{2}\right)$  and  $\left(-\frac{\sqrt{15}}{2}, -\frac{1}{2}\right)$ .
- The minimum value is f = -2 at (0, 2).

For a Python implementation check this file.

#### 1.1.2 Karush-Kuhn-Tucker theorem

**Ex.** 4 — Maximize f(x,y) = xy subject to  $100 \ge x + y$  and  $x \le 40$  and  $(x,y) \ge 0$ .

Answer (Ex. 4) — The Karush Kuhn Tucker (KKT) conditions for optimality are a set of necessary conditions for a solution to be optimal in a mathematical optimization problem. They are necessary and sufficient conditions for a local minimum in nonlinear programming problems. The KKT conditions consist of the following elements:

For an optimization problem in its standard form:

$$\max f(\mathbf{x})$$
s.t.  $g_i(\mathbf{x}) - b_i \leq 0 \quad i = 1, \dots, k$ 

$$g_i(\mathbf{x}) - b_i = 0 \quad i = k + 1, \dots, m$$

There are 4 KKT conditions for optimal primal ( $\mathbf{x}$ ) and dual ( $\lambda$ ) variables. If  $\mathbf{x}^*$  denotes optimal values:

- 1.Primal feasibility: all constraints must be satisfied:  $g_i(\mathbf{x}^*) b_i$  is feasible. Applies to both equality and non-equality constraints.
- 2.Gradient condition or No feasible descent: No possible improvement at the solution:

$$\nabla f(\mathbf{x}^*) - \sum_{i=1}^m \lambda_i^* \nabla g_i(\mathbf{x}^*) = 0$$

3. Complementariety slackness:

$$\lambda_i^*(g_i(\mathbf{x}^*) - b_i) = 0$$

4. Dual feasibility:  $\lambda_i^* \geq 0$ 

The last two conditions (3 and 4) are only required with inequality constraints and enforce a positive Lagrange multiplier when the constraint is active (=0) and a zero Lagrange multiplier when the constraint is inactive (>0). To solve our problem, first we will put it in its standard form:

$$\max f(x,y) = xy$$

$$g_1(x,y) = x + y - 100 \le 0$$
s.t.
$$g_2(x,y) = x - 40 \le 0$$

$$g_3(x,y) = -x \le 0$$

$$g_4(x,y) = -y \le 0$$
(1)

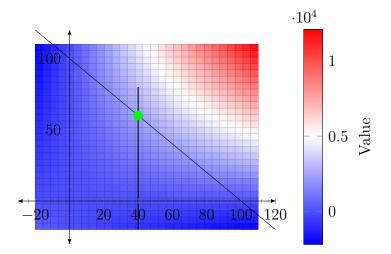

Figure 2: Contour plot of the objective function f(x, y) = xy with constraints in Eq. 1, showing the final optimal value after applying the KKT conditions (green dot).

We will go through the different conditions:

• on the gradient:

$$\begin{pmatrix} \frac{\partial f}{\partial x} \\ \frac{\partial f}{\partial y} \end{pmatrix} - \lambda_1 \begin{pmatrix} \frac{\partial g_1}{\partial x} \\ \frac{\partial g_1}{\partial y} \end{pmatrix} - \lambda_2 \begin{pmatrix} \frac{\partial g_2}{\partial x} \\ \frac{\partial g_2}{\partial y} \end{pmatrix} - \lambda_3 \begin{pmatrix} \frac{\partial g_3}{\partial x} \\ \frac{\partial g_3}{\partial y} \end{pmatrix} - \lambda_4 \begin{pmatrix} \frac{\partial g_4}{\partial x} \\ \frac{\partial g_4}{\partial y} \end{pmatrix} = 0$$

which, in this example, resolves into:

$$y - (\lambda_1 + \lambda_2 - \lambda_3) = 0 \tag{2}$$

$$x - (\lambda_1 - \lambda_4) = 0 \tag{3}$$

• on the complementary slackness:

$$\lambda_1(x + y - 100) = 0 \tag{4}$$

$$\lambda_2(x - 40) = 0 \tag{5}$$

$$\lambda_3 x = 0 \tag{6}$$

$$\lambda_4 y = 0 \tag{7}$$

• on the constraints:

$$x + y \le 100 \tag{8}$$

$$x \le 40 \tag{9}$$

$$-x \le 0 \tag{10}$$

$$-y \le 0 \tag{11}$$

plus  $\lambda_1, \lambda_2, \lambda_3, \lambda_4 \geq 0$ .

We will start by checking Eq. 4:

- -Let us see what occurs if  $\lambda_1 = 0$ . Then, from Eq. 3,  $x + \lambda_4 = 0$  which implies that  $x = \lambda_4 = 0^1$ . But, then, from Eq. 5 we obtain that  $\lambda_2 = 0$  which, using Eq. 2 gives  $y + \lambda_3 = 0 \Rightarrow y = \lambda_3 = 0$ . Indeed, the KKT conditions are satisfied when all variables and multipliers are zero, but it is not a maximum of the function (see figure above).
- -So, let us see what happens if x + y 100 = 0 and consider the two possibilities for x:

Case x = 0:Then, y = 100, which would lead (Eq. 7) to  $\lambda_4 = 0$  and (Eq. 3) to  $x = \lambda_1 = 0$ , that was discussed in the previous item. So, we need top explore the other possibility for x.

Case x > 0: From Eq. 6  $\lambda_3 = 0$  and, from Eqs. 2 and 3:

$$\begin{cases} y = \lambda_1 + \lambda_2 \\ x = \lambda_1 + \lambda_4 \end{cases}$$

let us try what happens if, e.g.,  $\lambda_2 \neq 0$  (or, said in other words, if constraint 9 is active): x = 40. As we know we do not want  $\lambda_1 = 0$ , from Eq. 4 we obtain  $x + y - 100 = 0 \Rightarrow y = 60$ .

The point (x, y) = (40, 60) fullfills the KKT conditions and is a maximum in the constrained maximization problem (as can be seen in Figure 2).

<sup>&</sup>lt;sup>1</sup>Recall that both variables and multiplieras must be positive or zero, so, the only possibility for the equation to fullfill is that both are zero.

## 1.2 Duality

Ex. 5 — Consider the linear programming problem:

Find  $x_1$ ,  $x_2$  and  $x_3$  to solve it.

Answer (Ex. 5) — material: complementary slackness.pdf

Ex. 6 — Consider the linear programming problem:

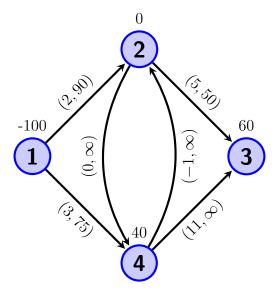

$$\max 2x_1 + 16x_2 + 2x_3$$
 
$$2x_1 + x_2 - x_3 \leq -3$$
 s.t. 
$$-3x_1 + x_2 + 2x_3 \leq 12$$
 
$$x_1, x_2x_3 \geq 0$$

Check whether each of the following is an optimal solution, using complementary slackness:

Answer (Ex. 6) — material: compslack.pdf

# 1.3 Network Analysis

**Ex. 7** — The figure shows a network on four nodes, including net demands on the vertex,  $b_k$ , and cost an capacity on the edges,  $(c_{i,j}, u_{i,j})$ . (Adapted from [1])

- 1. Formulate the corresponding minimum cost network flow model
- 2. Classify the nodes as source, sink or transhipment

**Answer (Ex. 7)** — In this problem, vertex and edges are:

$$V = \{1, 2, 3, 4\}$$

$$A = \{(1, 2), (1, 4), (2, 3), (2, 4), (4, 2), (4, 3)\}$$

we can use the variables  $x_{i,j}$  to represent the flows in the different members of set A. Thus, the formulation of the problem is:

of set A. Thus, the formulation of the problem is: 
$$\min \ 2x_{1,2} + 3x_{1,4} + 5x_{2,3} - x_{4,2} + 11x_{4,3}$$
 
$$= -100$$
 
$$x_{1,2} - x_{1,4} + x_{4,2} = 0$$
 
$$x_{2,3} + x_{4,3} = 60$$
 subject to 
$$\begin{cases} x_{1,2} - x_{2,3} - x_{2,4} + x_{4,3} = 60 \\ x_{2,3} + x_{4,3} - x_{4,2} = 40 \\ x_{1,2} - x_{2,3} - x_{2,4} - x_{4,3} - x_{4,2} = 40 \\ x_{1,2} - x_{2,3} - x_{2,4} -$$

and  $x_{i,j} \geq 0$ .

There are 4 KKT conditions for optimal primal (x4) and dual  $(\lambda)$  variables. If  $x^*$  denotes optimal values:

- 1. Primal feasibility: all constraints must be satisfied:  $g_i(x^*)-b_i$  is feasible. Applies to both equality and non-equality constraints.
- 2.Gradient condition or No feasible descent: No possible improvement at the solution:

$$\nabla f(x^*) - \sum_{i=1}^{m} \lambda_i^* \nabla g_i(x^*) = 0$$

3. Complementariety slackness:

$$\lambda_i^*(g_i(x^*) - b_i) = 0$$

4. Dual feasibility:  $\lambda_i^* \geq 0$ 

The last two conditions (3 and 4) are only required with inequality constraints and enforce a positive Lagrange multiplier when the constraint is active (=0) and a zero Lagrange multiplier when the constraint is inactive (>0). to solve our problem, first we will put it in its standard form:

$$\min f(x,y) = -xy$$
 subject to 
$$\begin{aligned} -x - y + 100 & \ge 0 \\ -x - 40 & \ge 0 \end{aligned}$$

We will go through the different conditions:

1. Primal feasibility:  $g_i(x^*) - b_i$  is feasible.

$$-x^* - y^* + 100 = 0$$
$$-x^* - 40 = 0$$

2. Gradient condition or No feasible descent:

$$\begin{pmatrix} \frac{\partial f}{\partial x} \\ \frac{\partial f}{\partial y} \end{pmatrix} - \lambda_1 \begin{pmatrix} \frac{\partial g_1}{\partial x} \\ \frac{\partial g_1}{\partial y} \end{pmatrix} - \lambda_2 \begin{pmatrix} \frac{\partial g_2}{\partial x} \\ \frac{\partial g_2}{\partial y} \end{pmatrix} = 0$$

which, in this example, resolves into:

$$\begin{cases} -y + \lambda_1 + \lambda_2 = 0 \\ -x - \lambda_1 = 0 \end{cases}$$

3. Complementariety slackness:

$$\lambda_1^*(-x^* - y^* + 100) = 0$$
$$\lambda_2^*(-x^* - 40) = 0$$

4. Dual feasibility:  $\lambda_1, \lambda_2 \geq 0$ 

We can put the resulting 5 expressions for conditions 1 and 2 into matrix form:

$$\begin{pmatrix} -1 & -1 & 0 & 0 \\ -1 & 0 & 0 & 0 \\ 0 & -1 & 1 & 1 \\ -1 & 0 & -1 & 0 \end{pmatrix} \begin{pmatrix} x \\ y \\ \lambda_1 \\ \lambda_2 \end{pmatrix} = \begin{pmatrix} -100 \\ 40 \\ 0 \\ 0 \end{pmatrix}$$
